ABSTRACT

This paper addresses how big data can be used to identify "food deserts", areas where there is no fresh, healthy food available to the population, to be used for community planning or research purposes.

KEYWORDS

food deserts, food insecurity, big data

1 INTRODUCTION

For many within the United States, ready access to affordable, nutritious food is a constant challenge. Many communities have no grocery store with supplies of various fresh foods, relying instead on convenience stores and fast food restaurants in order to find sustenance. These areas have come to be known as "food deserts".

It is estimated that 23.5 million Americans currently live in a food desert[6], and they have been linked to higher rates of childhood obesity, heart disease, and overall lower quality of life[5].

Up until recently, it has been difficult to define what a food desert actually is, and where to find them. However, researchers armed with big data have been able to make advances in identifying these problem areas and introducing solutions to help the people living there.

This paper will set a common definition with which to identify what a food desert is and where they are found. It will then showcase a few examples of government and private sector solutions to food deserts using big data through information sharing and classification.

2 DEFINITIONS

It will be useful to identify a common definition to operate on concerning "food deserts". Since it is a relatively new term, many differing definitions have been floated. For the purposes of this paper, we will use the definition given by the United States Department of Agriculture (USDA). According to the USDA, a food desert is any area that meets two criteria:

- (1) Low income, defined using poverty rate and median family income data. A community defined as "low-income" would have the following characteristics[6]:
 - (a) Poverty rate exceeding 20 percent
 - (b) A median family income being no greater than 80 percent of the median family income of the larger community
- (2) Low access, with at least one of the following characteristics[?]:

- (a) A. 33 percent of the population of the given area does not have the means (transportation) to reach a store, or
- (b) B. There is no store within their defined area.

3 IDENTIFYING PROBLEM AREAS

With the problem defined, the USDA set out to identify where in the United States were the areas that matched this criteria. All of the needed data was publicly available.

The USDA created their Food Access Research Atlas[1] in order to examine more carefully the similarities and differences between these areas. They used a variety of sources to inform the map where these areas existed:

- For general demographics, population, and rural/urban distinction they used data from the 2010 census.
- For income, vehicle availability, and food stamp participation they used data from the 2010-14 American Community Survey[3].
- For a comprehensive list of supermarkets and large grocery stores, they used two sources:
 - (1) A list of stores authorized to receive SNAP benefits (food stamps)
 - (2) A trade list from Trade Dimensions TDLinx[?].

This data was assigned to 1/2 kilometer squares for the most granular look possible at distinct food deserts within our cities and states. Using this information, they mapped out in detail where food deserts exist in the United States.[?]

Isolating the problem is vital, but only part of the solution. There are reasons these communities are without sufficient grocery options. For rural areas, the population density is often too low for companies to find it worthwhile to build a new store. For urban areas, increased crime levels often deter companies from finding a location desirable, even if it is in a densely populated area.[6]

However, unique solutions are emerging through the use of big data. Here are some examples of organizations using data such as that provided by the USDA to leverage solutions to those living in food deserts.

3.1 Online delivery

Normally, FreshDirect is used as a web-based produce delivery service catered towards a wealthier demographic. It provides fresh fruits and vegetables right to people's homes. But the company recently started a pilot program to bring online groceries to disadvantaged areas identified as not have ready access to fresh food.[4] The pilot program currently only exists in a few zip codes in New York, but it is proving effective.

The company is able to use card readers at delivery to charge the groceries to the recipients' SNAP benefits card - bringing fresh food to deserts and circumventing the problem of companies avoiding high-crime areas for brick-and-mortar businesses. The company is compiling data on the impact of the pilot program as they look at possible expansion.[4]

3.2 Charity matching

To many who live in food deserts, food pantries are an essential source of fresh food. These organizations used to be scattered and uncoordinated - donors did not know who to donate to, organizations had to rely on whatever foods happened to be dropped off in order to stock their shelves, and shoppers never knew what to expect when getting food.

That has changed with the Matching Excess and Need (MEANS) Database.[?] MEANS connects donors and food distributors algorithmically to find the best match - a fast and local pickup for the donor, and real-time notifications on donation matches for the distributors. The algorithm takes into account factors such as how quickly a charity responds and picks up items, how much and what quantity of foods a donor typically provides, and what items a pantry typically needs.[2] This application has been adopted by restaurants and grocery stores to reduce waste and find a willing recipient for their donation. It has been adopted in virtually every state and by major companies to eliminate waste and give back to the community.

4 CONCLUSIONS

Food deserts, and food scarcity in general, continues to be a major problem in our society. However, thanks to scarcity and demographic data being better collected and utilized, new solutions are being introduced to this age-old problem. There may not be simple solutions to bringing brick-and-mortar grocery stores back into underserved areas, but new technology applications powered by big data could be a vital path forward to circumventing the problem.

The path forward seems to be increased data collection, collaboration and information sharing between governments and private organizations (encompassing non-profits and corporations). This can be used to identify at an even more granular level individuals at risk of food scarcity. Organizations can then use this information to create applications and programs to address these needs:

- If companies like FreshDirect are any indication, companies who previously found that potential revenue from establishments in high-crime areas not being worth the risk may reexamine these areas and find profit may still be found using innovative online shopping tools paired with software reading SNAP benefit data.
- If organizations like MEANS are any indication, non-profits may find that a greater utilization of big data to streamline the pairing of donors to pantries may greatly affect their organization's impact on hunger. In addition, this innovation greatly impacts businesses as well, as they can use these services to donate foods that would have otherwise been thrown away. This benefits them from a monetary standpoint (tax write-offs) as well as a PR standpoint.

Big data applications are slowly but surely integrating into government, non-profit, and business functions. As we gain a greater understanding for the new concept of food deserts, hopefully data will continue to find ways to solve this problem.

6 ISSUES

no title

you do not use “quotes” properly

you need to *emphasize* and not “quote”

this is cool

Have you written the report in the specified format?

Have you included an acknowledgement section?

Have you included the paper in the submission system (In our class it is git)?

Have you specified proper identification in the submission system. This is typically a form or ASCII text that needs to be filled out (In our case it is a README.md file that includes a homework ID, names of the authors, and e-mails)?

Have you included all images in native and PDF format in the submission system?

Have you added the bibliography file that you managed (In our case jabref to make it simple for you)?

In case you used word have you also provided the jabref?

In case of a class and if you do a multi-author paper, have you added an appendix describing who did what in the paper?

Have you spellchecked the paper?

Are you using and the properly?

Have you made sure you do not plagiarize?

Is the title properly capitalized?

Have you not used phrases such as shown in the Figure below, but instead used as shown in Figure 3 when referring to the 3rd figure?

Have you capitalized fFigure 3f, fTable 1f, ... ?

Have you removed any figure that is not referred explicitly in the text (As shown in Figure ..)

Are the figure captions below the figures and not on top. (Do not include the titles of the figures in the figure itself but instead use the caption or that information?)

When using tables have you put the table caption on top?

Make the figures large enough so we can read the details. If needed make the figure over two columns?

Do not worry about the figure placement if they are at a different location than you think. Figures are allowed to float. If you want you can place all figures at the end of the report?

Are all figures and tables at the end?

In case you copied a figure from another paper you need to ask for copyright permission. In case of a class paper you must include a reference to the original in the caption.

Do not use the word fIf instead use we even if you are the sole author?

Do not use the phrase fIn this paper/report we showf instead use fWe showf. It is not important if this is a paper or a report and does not need to be mentioned.

Do not artificially inflate your paper if you are below the page limit and have nothing to say anymore.

If your paper limit is 12 pages but you want to hand in 120 pages, please check first ;-)

Do not use the characters & # % _ put a backslash before them

If you want to say and do not use & but use the word and.

Latex uses double single open quotes and double single closed quotes for quotes. Have you made sure you replaced them?

Pasting and copying from the Web often results in non ASCII characters to be used in your text, please remove them and replace accordingly.
